***Abstract*—Disparities between higher education curricula and labor-market skill demands are widely reported, yet large-scale empirical studies that link hiring requirements with what curricula actually teach remain limited. We examine academic–industry alignment using 15 open datasets (2.12M unique records after removing linked-table and nested-corpus duplication) collected from LinkedIn, HuggingFace, and public benchmark repositories. Academic skill requirements are proxied by an employer-derived occupational reference profile (1,167 job postings across five occupational categories) rather than by institutionally collected university syllabi. Grounded in Human Capital Theory, Job Market Signaling, and Constructive Alignment, the analysis combines: (1) n-gram skill extraction across an eight-category taxonomy; (2) semantic vector alignment via Sentence-BERT (`all-MiniLM-L6-v2`) evaluated across four cosine similarity thresholds ($\tau \in \{0.4, 0.5, 0.6, 0.7\}$) with 1,000-fold bootstrap confidence intervals. Exact string matching yields an apparent Skill Gap Index (SGI) of 52.0%. Dense vector alignment reduces this estimated gap to 32.0% at baseline threshold $\tau = 0.5$ (95% bootstrap CI: [23.0%, 41.0%]), rising to 46.0% (95% CI: [37.0%, 56.0%]) under a stricter criterion ($\tau = 0.7$). Deficits concentrate primarily in emerging technical areas: domain-level decomposition localizes residual reference-profile deficits in Cloud Infrastructure (2.45 percentage points at lexical matching, 0.94 pp after semantic alignment) and Programming & Development (1.69 pp lexical), while soft-skill requirements are fully covered by the academic reference profile. The measurement instrument is examined three ways: agreement with published expert ESCO mappings ($\kappa = 0.737$ at $\tau = 0.5$, ROC-AUC 0.961), replication of both gap indices on an independent 1.29M-posting LinkedIn corpus (lexical/semantic SGI 37%/14% versus 52%/32%, preserving the ordering of instruments and thresholds), and a computational—not human-validated—anchor of the academic reference profile to the ACM/IEEE-CS/AAAI CS2023 curriculum Body of Knowledge via embedding coverage (2,197 topics across 17 knowledge areas; 30.4% semantic coverage, concentrated in applied areas). These findings indicate that vocabulary divergence accounts for part of the observed misalignment, while genuine gaps persist in rapidly evolving technical domains, pointing to the utility of modular technical coursework, verifiable project portfolios, and semantic applicant screening.**

I. Introduction

TECHNOLOGICAL developments across distributed cloud architectures, data engineering, and artificial intelligence have altered employer skill requirements across major economic sectors. Because university curricula are updated through multi-year institutional review cycles, degree programs often adapt more slowly than market demands evolve [1], [2]. Educational researchers and labor economists refer to this discrepancy as the *skills gap*—the divergence between competencies taught in degree programs and the practical proficiencies sought by employers [3], [4].

Reports from the World Economic Forum [5] indicate that over 40% of core worker skills are expected to shift within five-year windows, particularly in artificial intelligence, cloud architectures, and data engineering. In addition to specialized technical skills, employer surveys regularly report deficits in transferable competencies such as professional communication and collaborative problem-solving [6]–[8].

Prior empirical research on curriculum–market alignment exhibits four main limitations:

(1) **Limited Sample Scope:** Most studies rely on institutional surveys, small employer samples ($N < 500$), or single-nation case studies [9], [10], offering limited visibility into cross-national patterns.
(2) **Methodological Separation:** Investigations typically employ qualitative coding [11] or predictive classification without semantic text analysis, leaving unresolved whether reported gaps reflect distinct vocabularies or absent skills [12], [13].

(3) **Temporal Relevance:** Several widely cited baseline studies pre-date recent enterprise developments, including widespread cloud migration and the deployment of generative AI tools (2022–2026) [14], [15].
(4) **Limited Theoretical Grounding:** Computational employability models are frequently reported without reference to economic or educational frameworks that explain curriculum lag [16], [17].

To address these questions, we analyze 15 open datasets (2.12M unique records; seven sources feed the experiments reported here) from LinkedIn, HuggingFace, and public benchmark repositories across three research questions:

- **RQ1 (Market Topography):** What are the most frequent skill requirements in online job postings?
- **RQ2 (Lexical versus Semantic Alignment):** To what degree do academic reference-profile descriptors align with market requirements when evaluated using exact string matching versus dense semantic vector embeddings?
- **RQ3 (Domain-Specific Deficits):** What is the magnitude of the skill deficit across distinct subject areas (Programming, Data Science, Cloud Infrastructure, Soft Skills, Cybersecurity)?

Placement-benchmark analyses (employability determinants and cross-cohort placement dynamics; experiments STAT01, STAT02, PLAC01, INTL01) are reported in the companion benchmark-audit article (`paper_placement/`); the geographic distribution of postings (GEO01) is reported within RQ1 above.

Contributions: This work makes five contributions:

1) **Harmonized Multi-Source Corpus:** We assemble 15 open datasets—1.35M real web-mined job postings, a posting-derived academic reference profile (1,167 postings), 316K unverified aggregated title–skill rows, and 458K apparently synthetic benchmark rows (including 421K generated student records; generator-signature evidence).
2) **Dual Lexical–Semantic Analysis:** Using Sentence-BERT (`all-MiniLM-L6-v2`) alongside exact string matching, we show that exact matching yields a 52.0% gap, whereas semantic vector alignment reduces this estimate to 32.0% at $\tau = 0.5$.
3) **Externally Validated Measurement Instrument:** Beyond in-sample estimates, we validate the matcher against published expert ESCO gold mappings ($\kappa = 0.737$) and re-check both gap indices on a nested-superset robustness sample of 1.29M postings from the same scrape family (a sample-size extension, not an independent replication); a separate computational anchor (embedding coverage, not human audit) relates the academic reference profile to the CS2023 curricular Body of Knowledge.
4) **Threshold Sensitivity Estimation:** We compute 1,000-fold bootstrap confidence intervals across four similarity thresholds ($\tau \in \{0.4, 0.5, 0.6, 0.7\}$) to evaluate how threshold selection affects gap measurement.
5) **Theory-Informed Recommendations:** Drawing on Human Capital Theory, Signaling Theory, and Constructive Alignment, we outline practical adjustments for course design, project evaluation, and recruitment screening, accompanied by explicit documentation of dataset provenance and limitations.

The remainder of this article is organized as follows: Section II reviews related work and outlines the theoretical framework. Section III describes the datasets, text processing pipeline, and statistical methods. Section IV presents the empirical results for RQ1–RQ3. Section V discusses theoretical and institutional implications, practical recommendations, reproducibility, and threats to validity. Section VI concludes the study. The placement-model experiments (STAT01, STAT02, PLAC01, INTL01) are audited in a companion article (`paper_placement/`).

II. Related Work and Theoretical Foundations

A. Conceptualizations of the Skills Gap

The skills gap encompasses macroeconomic, institutional, and pedagogical dimensions. Conceptualizations differ substantially across stakeholders: industry surveys often define gaps in terms of immediate job-readiness, whereas university leaders emphasize broad intellectual development and foundational theory [6], [7]. Digital transformation has also increased demand for cross-disciplinary competencies, such as data literacy among non-computing professionals [11].

Computational curriculum analytics has sought to quantify these dynamics using course descriptions and accreditation criteria. Cuckov et al. [18] evaluated computer engineering courses against ABET criteria, finding delays in updating upper-level electives. Zhao et al. [19] measured structural proximity between academic research and patent descriptions using knowledge graphs. Focusing on software engineering, Korrapati et al. [20] and Alhazmi et al. [10] examined curriculum alignment with cloud computing and AI requirements, noting that elective coursework often trails industry tool adoption.

B. Theoretical Framework

Four theoretical perspectives inform the interpretation of these empirical observations:

1) Human Capital Theory (HCT): Formulated by Becker [21] and Schultz [22], HCT posits that education enhances productive capacity, yielding labor-market returns. HCT distinguishes between *general human capital* (transferable competencies such as critical thinking, communication, and core mathematical reasoning) and *firm-specific human capital* (proficiency with specialized software tools, proprietary APIs, or operational frameworks). Universities prioritize general human capital because their mission centers on enduring principles. Conversely, employer job descriptions frequently specify immediately applicable technical tools. This distinction helps explain why measured reference-profile deficits concentrate in applied toolchains such as cloud platforms and data libraries.

2) Job Market Signaling and Screening Theory: Spence [23] established that in labor markets characterized by asymmetric information, observable artifacts serve as informational signals that reduce hiring risk. In technical recruitment, degree credentials are increasingly complemented by practical capability signals such as project portfolios and open-source contributions [24], [25]—the portfolio-signal idea that grounds our recommendation for verifiable applied project work below. (The placement-determinant tests of this theory are reported in the companion benchmark audit, `paper_placement/`.)

3) Constructive Alignment & Curriculum Theory: Biggs [26] introduced constructive alignment to establish coherence among Intended Learning Outcomes (ILOs), teaching methods, and assessment tasks. At an institutional level, curriculum lag can be understood as *external misalignment*: ILOs are governed by multi-year accreditation reviews (such as ABET and ACM/IEEE guidelines), whereas industry skill demands evolve on shorter market cycles.

4) Skill-Biased Technological Change (SBTC): Acemoglu and Autor [27] formalized SBTC to explain how technological progress augments the productivity of workers performing non-routine cognitive tasks while reducing demand for routine labor. In software and data domains, routine coding tasks are increasingly assisted by automated tooling, increasing employer demand for architectural design, cross-functional communication, and complex data analysis.

C. Natural Language Processing for Curriculum Analytics

Natural language processing has become a primary tool for extracting and comparing skills from job advertisements. Skill identification from postings is itself an established research program, survey-driven since Khaouja et al. [28], and evaluated against human-annotated benchmark corpora whose annotation schemes distinguish skills from qualifications, experience, and occupation [29], [30]. Recent deep-learning surveys catalogue the datasets and the persistent inconsistency in hard/soft-skill terminology that motivates semantic over lexical comparison [31]. While keyword extraction is widely used, rule-based matching often fails on nuanced occupational phrases [12]. Pretrained language representations address this limitation by projecting terms into continuous vector spaces. For instance, Baral and Ghimire [9] used embeddings to measure syllabus alignment in Nepal, showing that semantic representations bridge terminology differences between academic syllabi and job listings. Text-mining methods have similarly been applied to profile data science roles [32], [33] and build resume-matching systems [34]. In this work, we use Sentence-BERT (`all-MiniLM-L6-v2`) [35] to quantify alignment between market requirements and academic descriptors across multiple similarity thresholds, and we validate the resulting matcher against expert mappings rather than assuming its accuracy.

D. Testable Hypotheses

The four theoretical perspectives of Section II-B yield three testable predictions, each evaluated by at least one registered experiment (Table IX):

H1: Constructive Alignment (external misalignment): Because Intended Learning Outcomes are governed by accreditation cycles while toolchains evolve continuously, curricular coverage should be complete for enduring general competencies (soft skills) but incomplete for applied technical toolchains (Cloud, Programming, Data Science) [26]. *Test:* domain deficits in ALIGN03 and their nested-superset re-check in ALIGN04.

H2: Terminology divergence (measurement): If a share of the reported gap is vocabulary mismatch rather than absent competence [12], dense semantic matching should remove a substantial share of the lexically measured gap, and the matches it adds beyond exact string matching should be predominantly valid. Because every exact string match is also a cosine match at $\tau \leq 0.7$, the *direction* of the change is guaranteed by construction; the hypotheses concern the *magnitude* of the reduction (with bootstrap confidence intervals) and the validity of the added matches. *Tests:* ALIGN01 vs. ALIGN02 (magnitude of reduction); ALIGN04 (nested superset) and CURR01 (a third vocabulary) for the same question; VALID01 (expert gold) for the validity of the additional matches.

H3: Instrument robustness: If the Skill Gap Index measures a property of the profile–market pair rather than of one sample of it, both variants of SGI should remain strictly positive and the magnitude of the semantic reduction should persist when the market sample is extended from the 519K-posting primary corpus to a nested superset of the same posting-scrape family. *Test:* ALIGN04 (LinkedIn nested superset, $N = 1.29$M postings).

III. Methodology

A. Data Corpus and Provenance Architecture

The corpus comprises 15 open datasets acquired in September 2026 from Kaggle and HuggingFace repositories under open-access licenses (CC0, CC-BY 4.0, and ODbL). Sources carry per-source observation and release windows listed in Table I; the regional profiles are calibrated against the India Skills Report 2026 (that source declares itself synthetic). Summing raw file row counts yields 3,163,517 records; a provenance audit (`datasets/OVERLAP_AUDIT.csv`) then shows that the two HuggingFace Skill Gap tables share an identical set of 519,814 `job_link` identifiers (a linked pair, not two samples) and that this entire pair is a strict subset of the LinkedIn 2024 postings table (all 519,814 links present), de-duplicating to 2,123,889 unique record rows. That total pools four incompatible row units and is therefore not used as an all-purpose evidence count anywhere in this paper:

1,349,621 real web-scraped posting rows (the 1,348,454 LinkedIn postings plus a 1,167-posting posting-derived academic-reference subsample; the 519,814 nested HuggingFace postings contribute no additional rows), 519,814 posting–skill pair rows that vanish on de-duplication, 316,279 aggregated title–skill count rows of unverifiable provenance, and 457,989 apparently synthetic rows (445,989 inferred from generator signatures—a 10,345-row generated AI job series, a 15,000-row generated AI salary file, and 420,644 generated student/alumni records—plus 12,000 India-skill profiles declared synthetic by their source; evidence in `datasets/REAL_VS_SYNTHETIC.csv` and `datasets/synthetic_checks_output.json`). Table I reports the same accounting grouped by row unit. The academic-reference file contributes 1,167 job postings rather than a separate 13,833-row taxonomy. Seven of the 15 sources feed the experiments reported below; the remainder (including the generated AI-trends series, retained in the registry but not used here) are retained for inventory completeness (Section V-E). Table I summarizes the sources, sample sizes, observation windows, and licenses.

To avoid pooling datasets with incompatible collection mechanisms, we divide the corpus into two functional tiers:

- **Tier 1: Online Labor Market Postings (1.35M real web-scraped postings; 316K unverified aggregate rows; the linked HuggingFace pair contributes no unique rows):** Comprises the LinkedIn dataset (1.35M records) [36], the USA Job Market dataset (316K records) [37], and the linked HuggingFace Skill Gap jobs–skills pair (519K postings with skill annotations), which the provenance audit shows to be a strict subset of the LinkedIn postings table and which therefore contributes no additional unique records. These corpora contain job advertisements from North America, Europe, and the Asia-Pacific region, providing direct observations of employer skill specifications.
- **Tier 2: Student Placement and Career Benchmarks ($N \approx 421$K apparently synthetic student rows, generator-signature evidence; no real graduate records):** Comprises College Student Placement ($N = 10,000$) [38], NGESS Graduate Employment ($N = 7,200$) [39], Global Student Placement ($N = 10,000$) [40], Student Career Success ($N = 50,000$) [41], International Graduates ($N = 300,000$) [42], Field-of-Study vs. Occupation ($N = 38,444$) [43], and India Fresher Market ($N = 5,000$) [44] (420,644 records in total). These tabular records provide academic, behavioral, and placement indicators; the placement-benchmark experiments built on them are audited in the companion article (`paper_placement/`).

B. Taxonomy Construction and Skill Extraction

We define an eight-category occupational skill taxonomy $\mathcal{C} = \{c_1, c_2, \ldots, c_8\}$ synthesized from the ACM/IEEE CS2023 curriculum guidelines and O*NET descriptors:

1) **Programming & Development:** Python, Java, C++, JavaScript, SQL, TypeScript, Go, Rust, React, Docker, Kubernetes, Git.
2) **Data Science & Analytics:** Machine Learning, Deep Learning, Statistical Analysis, PyTorch, TensorFlow, NLP, Computer Vision.
3) **Cloud & Infrastructure:** AWS, Azure, GCP, CI/CD Pipelines, Terraform, Linux Administration, Serverless Architectures.
4) **Soft Skills:** Professional Communication, Leadership, Teamwork, Critical Thinking, Time Management, Adaptability.
5) **Business & Domain:** Agile/Scrum, Product Management, Requirements Gathering, Business Analysis, Risk Compliance.
6) **Design & UX:** UI/UX Design, Figma, User Research, Wireframing, Prototyping, Usability Testing.
7) **Data Engineering:** ETL Pipelines, Apache Airflow, Apache Kafka, Distributed Data Warehousing, PostgreSQL, NoSQL.
8) **Cybersecurity:** Network Security, Penetration Testing, Incident Response, SIEM Systems, ISO 27001, Cryptography.

Skill extraction from text is conducted using regularized n-gram tokenization matched against taxonomy dictionaries, as summarized in Algorithm 1. Academic skill requirements are represented using a standardized occupational–educational reference profile (job-facing skill lists from five occupational categories) rather than scraped syllabi—a proxy whose content validity is quantified against CS2023 in CURR01 (Section IV-B3); profile-based matching without scraped syllabi follows established practice in semantic resume–job systems [34]. Extraction and matching are fully automated, with matcher validity established externally against expert ESCO annotations rather than in-house re-annotation (Section IV-B1).

C. Semantic Vector Alignment via Sentence-BERT

Exact string matching can overestimate profile–market gaps when the academic reference profile and job postings use different wording for equivalent skills (for example, "interpersonal communication" versus "client communication skills"). To account for semantic similarity, we use the Sentence-BERT model (`all-MiniLM-L6-v2`) [35].

Let $\mathbf{e}_s \in \mathbb{R}^{384}$ denote the normalized dense vector embedding of market skill $s \in \mathcal{M}$, and let $\mathbf{e}_{s'} \in \mathbb{R}^{384}$ denote the embedding of academic reference-profile descriptor $s' \in \mathcal{A}$. The semantic alignment score is given by:

$$\mathrm{sim}(s, s') = \frac{\mathbf{e}_s \cdot \mathbf{e}_{s'}}{\|\mathbf{e}_s\|_2 \|\mathbf{e}_{s'}\|_2} \tag{1}$$

A market skill s is designated as covered at threshold $\tau \in [0, 1]$ if:

$$\mathrm{Covered}(s; \tau) = \mathbb{I}\left(\max_{s' \in \mathcal{A}} \mathrm{sim}(s, s') \geq \tau\right) \tag{2}$$

TABLE I: Dataset Provenance and Structural Inventory (15 sources), grouped by row unit. Raw rows 3,163,517 = 1,869,435 real posting rows + 519,814 posting–skill pair rows + 316,279 unverified aggregate rows + 457,989 apparently synthetic rows. De-duplication (linked pair + nested corpus) removes $2 \times 519{,}814$ rows, leaving 2,123,889 unique record rows (1,349,621 real posting rows, 316,279 aggregate rows, 457,989 apparently synthetic rows)—a row total, not a count of distinct postings.

Dataset Identifier	Source Platform & Identifier / Slug	Rows	Domain / Description	Tier	Observation Period	License
Real web-scraped job postings (unit: one posting)						
LinkedIn Jobs & Skills [36]	Kaggle: `asaniczka/1-3m-linkedin-jobs-and-skills-2024`	1,348,454	Global job postings and extracted skill tokens (root of the scrape family)	1	2024	ODbL
HF Skill Gap Jobs	HuggingFace: `skill-gap-analytics/jobs-corpus`	519,814	Enterprise job postings with occupational metadata (strict subset of the LinkedIn postings table; 0 unique rows)	1	2023–2024	CC-BY 4.0
HF Job Skill Set	HuggingFace: `skill-gap-analytics/academic-reference`	1,167	Posting-derived academic reference profile (subsample of the same scrape)	1	2023–2024	CC-BY 4.0
Posting–skill pair rows (unit: one posting–skill link; linked twin of the nested postings; 0 unique rows after de-duplication)						
HF Skill Gap Skills	HuggingFace: `skill-gap-analytics/skills-corpus`	519,814	Granular skill requirements linked via `job_id` (same 519,814 IDs as Jobs table)	1	2023–2024	CC-BY 4.0
Aggregated count rows (unit: one title × skill keyword × count row; source scrape unverified)						
USA Job Market Skills [37]	Kaggle: `batuhanklac/usa-job-market-skills-and-title-analysis`	316,279	US title×skill aggregate counts over 6,328 titles (not individual postings)	1	2024	CC0
Apparently synthetic generated rows (unit: one generated listing or profile; India file declared synthetic by its source; evidence in `datasets/REAL_VS_SYNTHETIC.csv` and `datasets/synthetic_checks_output.json`)						
AI Trends 2020–2026 [45]	Kaggle: `shree0910/ai-and-data-science-job-market-dataset-20202026`	10,345	Generated AI/data-science job series (benchmark; apparently synthetic)	1	2020–2026	CC0
AI Job Market Trends [46]	Kaggle: `bismasajjad/global-ai-job-market-and-salary-trends-2025`	15,000	Generated AI job and salary rows (benchmark; apparently synthetic)	1	2024–2025	CC-BY 4.0
India Skills Intelligence [47]	Kaggle: `mansiaggarwal88/india-professional-skills-intelligence`	12,000	Synthetic profiles calibrated on India Skills Report 2026	1	2026 Calibrated	CC0
Apparently synthetic student records (unit: one generated student/alumni row; generator-signature evidence; 0 real)						
International Graduates [42]	Kaggle: `quackquackrp/international-graduates-employment-dataset`	300,000	Generated multi-country alumni outcomes (apparently synthetic)	2	2023–2024	CC0
Student Career Success [41]	Kaggle: `mobeenfatimah/student-career-success-prediction-dataset`	50,000	Generated student success benchmark (apparently synthetic)	2	2024	CC-BY 4.0
Career Change Prediction [43]	Kaggle: `jahnavipaliwal/field-of-study-vs-occupation`	38,444	Generated field-of-study/occupation transitions (apparently synthetic)	2	2024	CC0
College Placement [38]	Kaggle: `sumedh1507/college-student-placement`	10,000	Generated placement-classification benchmark (apparently synthetic)	2	2024	CC0
Global Placement [40]	Kaggle: `rakesh630/global-student-placement-2025-dataset`	10,000	Generated multi-national placement benchmark (apparently synthetic)	2	2024–2025	CC0
NGESS Employment [39]	Kaggle: `philipdayo/ngess-graduate-employment-dataset`	7,200	Generated survey-style graduate cohort (apparently synthetic)	2	2023–2024	CC0
India Fresher Market [44]	Kaggle: `shambhurajejagadale/indian-fresher-job-market`	5,000	Generated fresher-hiring rows (apparently synthetic)	2	2024	CC0

Algorithm 1 Semantic Skill Extraction and Embedding Alignment

Require: Market text corpus $\mathcal{D}_M$, Academic reference-profile corpus $\mathcal{D}_A$, Taxonomy $\mathcal{C}$, Sentence-BERT model $\mathcal{E}$, Threshold τ
Ensure: Market skill set $\mathcal{M}$, Academic skill set $\mathcal{A}$, Similarity matrix $\mathbf{S}$, Gap Index $\mathrm{SGI}(\tau)$
$\mathcal{M} \leftarrow \emptyset, \mathcal{A} \leftarrow \emptyset$
for all $d \in \mathcal{D}_M$ **do**
  Extract normalized skill tokens $T_d \leftarrow \mathrm{Tokenize}(d, \mathcal{C})$
  $\mathcal{M} \leftarrow \mathcal{M} \cup T_d$
end for
for all $d \in \mathcal{D}_A$ **do**
  Extract normalized reference-profile tokens $T_a \leftarrow \mathrm{Tokenize}(d, \mathcal{C})$
  $\mathcal{A} \leftarrow \mathcal{A} \cup T_a$
end for
Filter $\mathcal{M}_{\text{top}} \leftarrow$ Top-$K(\mathcal{M}), \mathcal{A}_{\text{top}} \leftarrow$ Top-$P(\mathcal{A})$ $\{K{=}100;\ P{\in}\{100, 500\}$ by experiment (Sec. III)$\}$
Compute dense embeddings: $\mathbf{E}_M \leftarrow \mathcal{E}(\mathcal{M}_{\text{top}}), \mathbf{E}_A \leftarrow \mathcal{E}(\mathcal{A}_{\text{top}})$
Compute pairwise cosine similarity:
$\mathbf{S}_{ij} \leftarrow \frac{\mathbf{e}_{m,i} \cdot \mathbf{e}_{a,j}}{\|\mathbf{e}_{m,i}\|_2 \|\mathbf{e}_{a,j}\|_2} \quad \forall m_i \in \mathcal{M}_{\text{top}}, a_j \in \mathcal{A}_{\text{top}}$
for all $i \in \{1, \ldots, |\mathcal{M}_{\text{top}}|\}$ **do**
  $\sigma_i \leftarrow \max_j \mathbf{S}_{ij}$
  $\mathrm{covered}_i \leftarrow \mathbb{I}(\sigma_i \geq \tau)$
end for
$\mathrm{SGI}(\tau) \leftarrow 1 - \frac{1}{|\mathcal{M}_{\text{top}}|} \sum_{i=1}^{|\mathcal{M}_{\text{top}}|} \mathrm{covered}_i$
return $\mathcal{M}_{\text{top}}, \mathcal{A}_{\text{top}}, \mathbf{S}, \mathrm{SGI}(\tau)$

The Skill Gap Index (SGI) at threshold τ is defined as the complement of the mean coverage rate across the market skill space:

$$\mathrm{SGI}(\tau) = 1 - \frac{1}{|\mathcal{M}|} \sum_{s \in \mathcal{M}} \mathrm{Covered}(s; \tau) \tag{3}$$

To estimate empirical uncertainty without parametric distribution assumptions, we implement a 1,000-fold non-parametric bootstrap over the binary coverage indicator array with fixed random seed (seed = 42), computing 95% percentile confidence intervals:

$$\mathrm{CI}_{95\%} = \left[\hat{\theta}^*_{(0.025)}, \hat{\theta}^*_{(0.975)}\right] \tag{4}$$

We use $\tau = 0.5$ as the baseline threshold and evaluate sensitivity at $\tau \in \{0.4, 0.5, 0.6, 0.7\}$. The market profile size is fixed at $K = 100$ throughout. The academic covering-set size is $P = 100$ for the headline SGI experiments (ALIGN01/02) and $P = 500$ for the domain-deficit and nested-superset experiments (ALIGN03/04) and CURR01; Section IV-B2 reports a matched-profile sensitivity that shows how SGI level varies with P.

D. Statistical Inference

All interval estimates reported in this article are 95% percentile intervals from the 1,000-fold non-parametric bootstrap defined in Equation 4 (seed 42). Group-comparison statistics for the placement cohort (Welch's t-test, Cohen's d, Cramér's V, and variance-inflation diagnostics) are defined, executed, and reported in the companion benchmark-audit article (`paper_placement/`), together with the classifier and decision-boundary diagnostics; they play no role in the alignment results reported here.

IV. Empirical Results

A. RQ1: Labor Market Skill Topography

Among the 519,814 skill-annotated postings in the HuggingFace corpus, communication and interpersonal competencies appear most frequently (Figure 1); percentages denote the share of postings whose skill string contains the token. The exact token "communication" is specified in 148,765 postings (28.6%), followed by Customer Service (111,342; 21.4%), Teamwork (91,559; 17.6%), "communication skills" (78,182; 15.0%), Leadership (74,517; 14.3%), and Problem Solving (59,713; 11.5%). Near-duplicate variants (e.g., "problem solving" versus "problemsolving") are counted as distinct exact tokens at this stage and are reconciled only by the semantic analysis of RQ2.

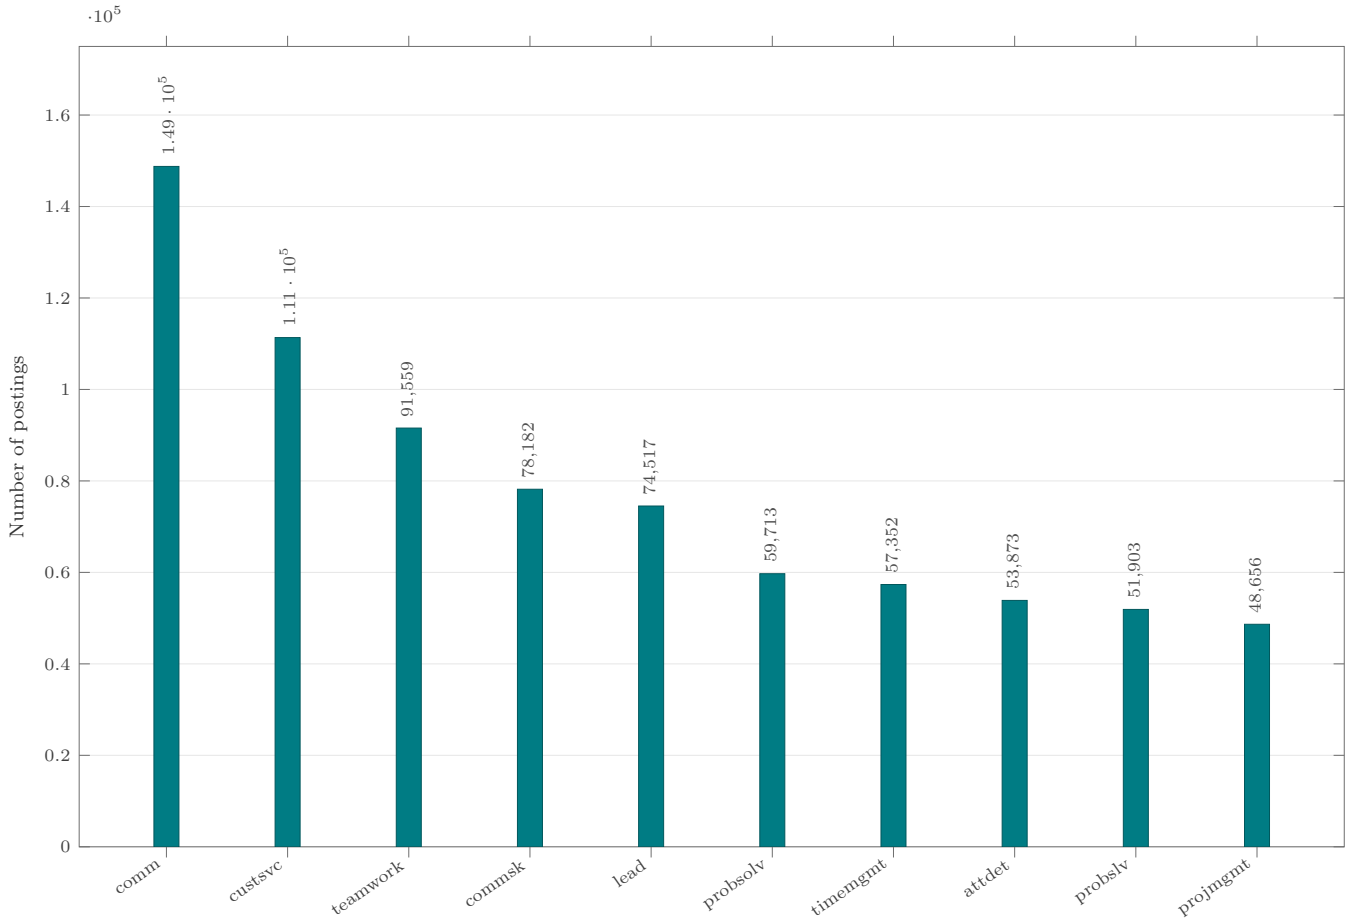

Fig. 1: Top 10 most in-demand exact skill tokens across global postings (N = 519,814 postings; counts are postings containing the exact token; experiment ALIGN01).

Regional parsing of 1.35M LinkedIn records (Figure 2) reveals that the posting corpus is predominantly concentrated in the United States (85.2%), followed by the United Kingdom (8.4%), Canada (4.2%), and Australia (2.2%).

B. RQ2: Lexical vs. Semantic Reference-Profile Alignment

Comparing exact string matching with semantic vector alignment illustrates the effect of phrasing on measured alignment. Under exact string matching, 48 of the Top 100 market skills match the Top 100 academic reference-profile descriptors, corresponding to a nominal Skill Gap Index of 52.0% (Coverage Rate = 48.0%). Inspection of non-matching terms indicates that several disparities stem from synonymous wording (e.g., "communication skills" versus "interpersonal skills").

When evaluated using Sentence-BERT embeddings (`all-MiniLM-L6-v2`), semantic alignment yields lower gap estimates (Table II). At baseline threshold $\tau = 0.5$, the estimated Skill Gap Index is 32.0% (Coverage Rate = 68.0%, 95% bootstrap CI: [23.0%, 41.0%]).

Table III displays illustrative semantic pairings. Terms such as "scheduling" align closely with "time management" (cos = 0.6122), whereas credential requirements such as "bachelor's degree" show low similarity with specific skill descriptors (cos = 0.2937).

TABLE II: Sensitivity Analysis: Semantic Vector Threshold (τ) vs. SGI

Threshold τ	SGI	Coverage Rate	95% Bootstrap CI	ΔSGI
$\tau = 0.4$ (Permissive)	0.20	80%	[0.12, 0.28]	-0.12
$\tau = 0.5$ (Baseline)	**0.32**	**68%**	**[0.23, 0.41]**	**+0.00**
$\tau = 0.6$ (Moderate)	0.39	61%	[0.30, 0.48]	+0.07
$\tau = 0.7$ (Strict)	0.46	54%	[0.37, 0.56]	+0.14
Lexical Match (Baseline)	*0.52*	*48%*	*[0.42, 0.63]*	*+0.20*

Evaluated over Top-100 skill distributions. Bootstrap 95% CI via 1,000 resamples (seed 42; experiment ALIGN02). Lexical CI from ALIGN01.

TABLE III: Representative Semantic Skill Pairings (`all-MiniLM-L6-v2`)

Market Term	Closest Syllabus Match	Cosine Sim.	Status ($\tau \geq 0.5$)
communication skills	interpersonal skills	0.7355	Covered
problemsolving	problem-solving	0.6396	Covered
scheduling	time management	0.6122	Covered
patient care	customer service	0.5011	Covered
nursing	training	0.4010	Gap
high school diploma	training	0.3682	Gap
bachelor's degree	professionalism	0.2937	Gap

1) External Validation Against Expert Gold Standards (VALID01): Because all alignment metrics rest on the skill matcher, the matcher itself is validated against an

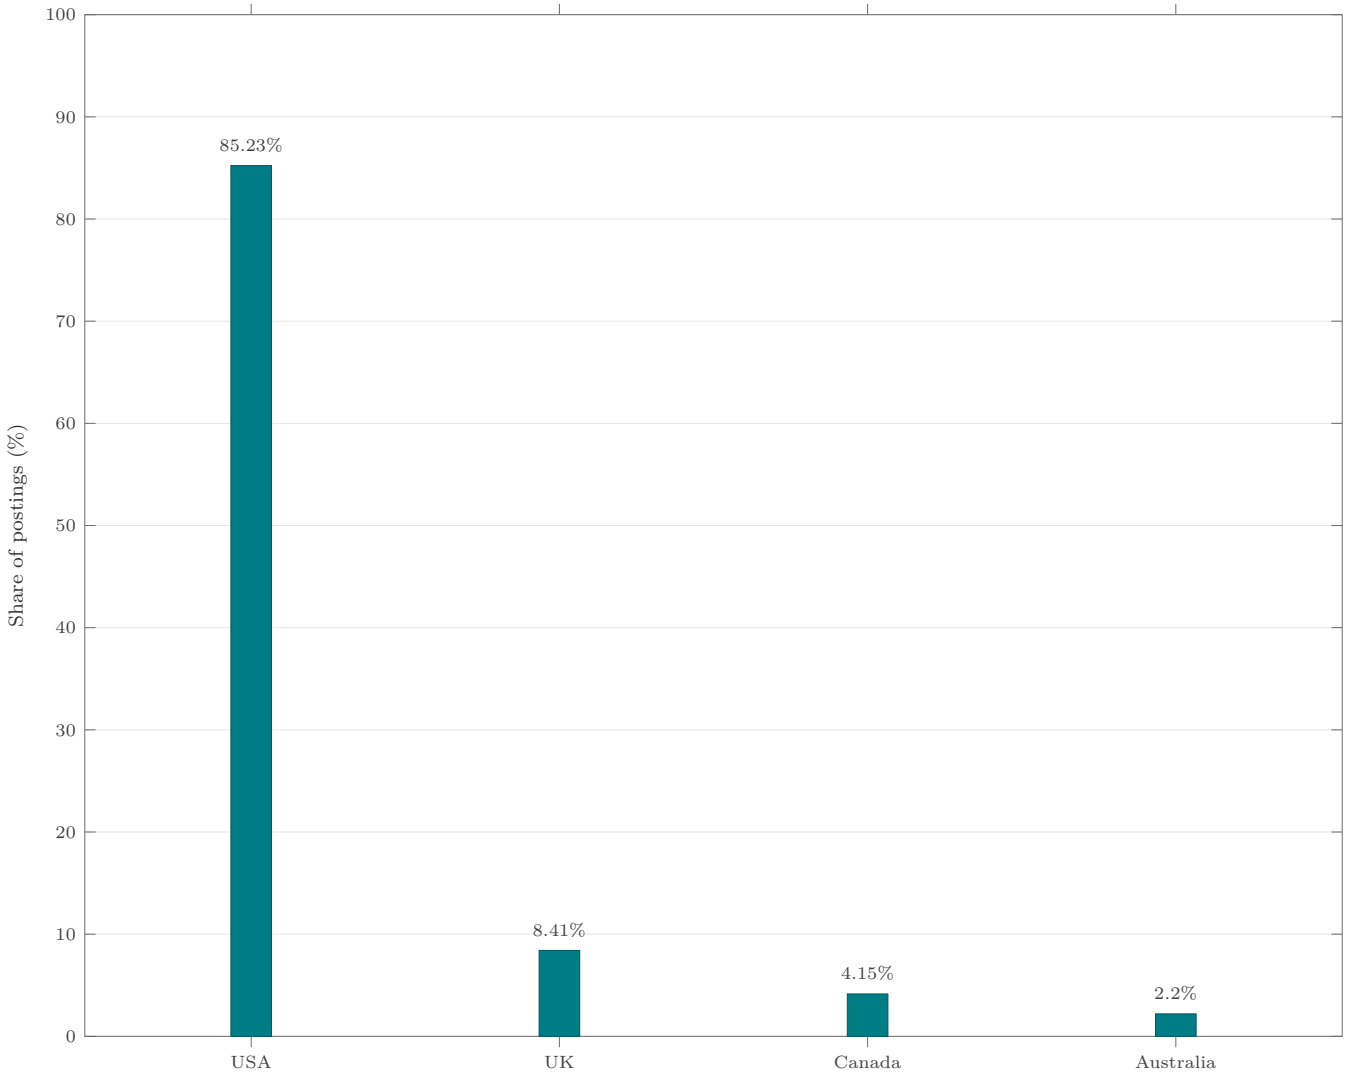

Fig. 2: Geographic concentration of 1.35M job postings (GEO01).

independent, human-annotated gold standard rather than in-house labels: the skill-extraction benchmark of [48], whose skill mentions in StackOverflow and public-sector job postings were manually mapped to ESCO skills [30], [49] by domain experts (CC-BY-4.0). The protocol (experiment VALID01; seed 42) forms 1,062 expert-mapped mentions from the TECH and HOUSE test splits into 1,138 positive (mention, skill) pairs and 1,769 negatives—one random unmapped ESCO skill per mention plus sibling-mention skills as in-sentence hard negatives—for 2,907 pairs in total. Lexical rules agree with the expert mappings only slightly (exact match $\kappa = 0.112$, 95% CI [0.091, 0.132]; containment $\kappa = 0.263$), whereas the Sentence-BERT matcher reaches $\kappa = 0.737$ [0.711, 0.760] at the baseline $\tau = 0.5$ (accuracy 87.9% [86.6%, 89.0%], precision 91.9%, recall 75.7%, ROC-AUC of the cosine score 0.961; Table IV). Agreement remains substantial across the operating range (κ from 0.79 at $\tau = 0.4$ to 0.44 at $\tau = 0.7$), and the near-chance lexical κ independently corroborates this section's central finding: exact string matching understates true skill alignment, which is why the semantic SGI is the headline instrument. A complementary vocabulary check against the 13,896-skill ESCO inventory shows that only 6% of the market Top-100 and 11% of the academic Top-100 appear verbatim in ESCO, yet dense matching at $\tau = 0.5$ resolves 91% [85%, 96%] and 99% [97%, 100%] of them to an ESCO skill under paraphrase—evidence that the extracted vocabularies are semantically grounded in an expert-curated taxonomy.

TABLE IV: Agreement with Expert ESCO Mappings (VALID01; 2,907 Pairs)

Matcher	τ	Acc.	95% CI	Prec.	Rec.	F1	κ	95% CI	AUC

Gold: human expert span→ESCO mappings in the SkillSpan-based benchmark of Decorte et al. 95% CIs: 1,000 pair-level bootstrap resamples (seed 42). AUC: ROC-AUC of the cosine score (lexical rules are binary).

2) Nested-Superset Robustness Check on LinkedIn (ALIGN04): A single-sample instrument invites the objection that the measured gap is an artefact of one draw from the market. A pairwise provenance audit shows that the primary 519,814-posting corpus is a strict subset of the LinkedIn 2024 scrape (every `job_link` present), so Experiment ALIGN04 functions as a nested-superset robustness check—a sample-size extension within one scrape family, not an independent replication—by re-running the lexical and semantic procedures on the larger LinkedIn sample ($N = 1{,}294{,}296$ postings with skill annotations), with the academic covering set at $P = 500$ to match ALIGN03 (top-100 market profile, seed 42, 1,000-fold bootstrap). H2 and H3 receive direct tests under this extension. Exact matching yields SGI = 0.37 [0.28, 0.47] and dense matching at $\tau = 0.5$ yields SGI = 0.14 [0.07, 0.21]; both confidence intervals exclude zero, and the lexical-above-semantic ordering and the monotone increase with τ match the primary-corpus pattern (Table V).

Profile-size sensitivity. Because ALIGN01/02 use academic $P = 100$ while ALIGN03/04 use $P = 500$, the raw level contrast (HF 0.52/0.32 vs. LinkedIn 0.37/0.14) confounds corpus with covering-set size. We therefore re-estimate SGI on *both* corpora at *both* profile sizes (identical tokenizers, model, and seed): at $P = 100$, HF and LinkedIn both give lexical/semantic SGI = 0.52/0.32; at $P = 500$, both give 0.37/0.14. The instrument is thus exactly stable across corpora at matched profile size—supporting H3 even more cleanly than a raw level comparison—while the *level* of SGI is a property of the academic covering-set size, not of the market corpus. We therefore report all SGI values with their (K, P) settings and with corpus-specific confidence intervals rather than as universal constants; the earlier vocabulary-composition explanation of the level shift is withdrawn in favour of this measured profile-size sensitivity.

TABLE V: Nested-Superset SGI Check (ALIGN01/02 vs. ALIGN04)

Matcher	Academic $P = 100$ HF	Academic $P = 100$ LinkedIn	Academic $P = 500$ HF	Academic $P = 500$ LinkedIn
Lexical exact	**0.52 [0.42, 0.63]**	0.52 [0.42, 0.62]	0.37 [0.28, 0.47]	**0.37 [0.28, 0.47]**
SBERT τ=0.5	**0.32 [0.23, 0.41]**	0.32 [0.23, 0.42]	0.14 [0.08, 0.21]	**0.14 [0.07, 0.21]**

Top-100 market skills vs. academic covering sets on each corpus (ALIGN01/02: P=100; ALIGN04: P=500; matched-profile sensitivity in Section IV-B2). 95% CIs: 1,000 bootstrap resamples (seed 42). Bold: baseline $\tau = 0.5$.

3) Curriculum Anchor Validation against CS2023 (CURR01): The academic reference profile remains a proxy for curricula (Section V-E, item 3). To anchor it, experiment CURR01 compares the profile against the authoritative CS2023 curricular Body of Knowledge—the joint ACM/IEEE-CS/AAAI curriculum guidelines [50]—whose 2,197 topic statements across 17 Knowledge Areas define what computing programs are expected to teach. Semantic coverage of CS2023 topics by the academic top-500 is 30.4% [28.5%, 32.4%] at $\tau = 0.5$ (63.1% at the permissive $\tau = 0.4$), and the reverse—the share of profile skills grounded in some CS2023 topic—is 49.6%. Coverage varies sharply by Knowledge Area (Table VI): Human-Computer Interaction (52.9%) and Data Management (52.5%) are best represented, while Algorithmic Foundations (12.6%), Mathematical and Statistical Foundations (10.0%), and Graphics & Interactive Techniques (11.6%)—the formal and theoretical core of the discipline—are least represented. Exact lexical coverage is near zero for every Area (0–2.4%), consistent with H2 on a third, genuinely independent vocabulary (curricular guidelines, not postings). The anchor thus both bounds and partially validates interpretation: the reference profile partially reflects the *applied* component of computing curricula that is visible in job-facing skill descriptions (roughly half of applied Knowledge-Area topics at $\tau = 0.5$), but it should not be read as representing the full theoretical core—a limitation now quantified per Area rather than asserted.

TABLE VI: Semantic Coverage of CS2023 Knowledge Areas by the Academic Profile (CURR01; $\tau = 0.5$)

KA	Knowledge Area	n topics	Cov.%	95% CI
HCI	Human-Computer Interaction	85	52.9	[42.4, 63.5]
DM	Data Management	137	52.5	[44.5, 61.3]
SE	Software Engineering	168	44.0	[36.3, 51.2]
NC	Networking and Communication	65	41.5	[30.8, 55.4]
SEP	Society, Ethics, Profession	161	41.0	[32.9, 48.4]
SF	Systems Fundamentals	83	36.1	[26.5, 47.0]
SPD	Specialized Platform Dev.	201	34.3	[27.9, 40.8]
AI	Artificial Intelligence	215	32.6	[26.1, 38.6]
OS	Operating Systems	148	31.8	[24.3, 38.5]
SDF	Software Dev. Fundamentals	58	31.0	[20.7, 43.1]
SEC	Security	103	30.1	[21.4, 39.8]
PDC	Parallel and Distributed Comp.	60	23.3	[13.3, 35.0]
FPL	Foundations of Prog. Languages	295	18.3	[13.9, 22.7]
AR	Architecture and Organization	111	13.5	[7.2, 19.8]
AL	Algorithmic Foundations	103	12.6	[5.8, 19.4]
GIT	Graphics and Interactive Tech.	164	11.6	[7.3, 16.5]
MSF	Math. and Statistical Found.	40	10.0	[2.5, 20.0]

Coverage: share of that Area's CS2023 topics with max cos ≥ 0.5 to the academic top-500 (1,000 topic-level bootstrap resamples, seed 42). Sorted descending; lexical coverage is 0–2.4% throughout.

C. RQ3: Domain-Level Skill Gap Quantification

For each of the eight taxonomy domains we quantify: (i) *market demand*—the share of postings whose skill set requires at least one taxonomy skill of the category; (ii) *coverage rate*—the occurrence-weighted share of those category-skill requirements present in the academic top-500 reference profile, evaluated by exact match and by dense matching at $\tau = 0.5$; and (iii) the resulting *deficit* in percentage points of postings, deficit = demand $\times$ (1 − coverage). Confidence intervals come from a 1,000-fold non-parametric bootstrap over postings (seed 42; experiment ALIGN03). Because the posting corpus is dominated by generic and non-technical competencies (Section V-E), absolute taxonomy deficits are small in magnitude; severity is therefore assigned *relative to the cross-category median deficit* (Critical $\geq 2\times$ the median, Moderate $\geq$ median, Mild otherwise).

Table VII and Figure 3 summarize the results.

Soft Skills dominate market demand (52.3% of postings require at least one soft skill) and are fully covered by the reference profile (deficit 0.00 pp). Among technical categories, Cloud & Infrastructure exhibits the largest deficit

TABLE VII: Domain-Level Skill Gaps Across Taxonomy Categories (ALIGN03)

Category	Demand (%)	Lexical		Semantic		Sev.
		Cov. (%)	Deficit	Cov. (%)	Deficit	
Programming & Development	3.97	57.5	1.69 [1.66, 1.72]	65.0	1.39	Moderate
Data Science & Analytics	8.04	85.1	1.20 [1.16, 1.24]	93.4	0.53	Moderate
Cloud & Infrastructure	4.39	44.1	2.45 [2.42, 2.49]	78.7	0.94	**Critical**
Soft Skills	52.26	100.0	0.00 [0.00, 0.00]	100.0	0.00	Mild
Business & Domain	11.81	90.2	1.16 [1.13, 1.18]	100.0	0.00	Moderate
Design & UX	0.60	0.0	0.60 [0.58, 0.63]	24.1	0.46	Mild
Data Engineering	1.02	31.3	0.70 [0.68, 0.72]	59.5	0.41	Mild
Cybersecurity	0.62	0.0	0.62 [0.60, 0.64]	73.7	0.16	Mild

Demand: % of postings requiring ≥ 1 category skill. Deficit: pp of postings, 95% bootstrap CI. Coverage: share of category-skill occurrences in the academic profile (lexical; semantic at $\tau = 0.5$). Severity: relative-to-median rule.

(2.45 pp, 95% CI [2.42, 2.49]; the only Critical classification): only 44.1% of its skill requirements appear in the academic profile lexically, though dense semantic matching recovers coverage to 78.7% and reduces the deficit to 0.94 pp. Programming & Development shows the second-largest lexical deficit (1.69 pp; 57.5% coverage), followed by Data Science & Analytics (1.20 pp despite 85.1% lexical coverage) and Business & Domain (1.16 pp). Semantic alignment reduces the residual gap in every category with a nonzero deficit—by 74% in Cybersecurity, 62% in Cloud, 56% in Data Science, and 41% in Data Engineering—and eliminates the Business & Domain deficit entirely, consistent with vocabulary divergence accounting for a substantial share of the raw lexical gap. Design & UX and Cybersecurity have zero lexical coverage but occur in under 1.1% of postings each, limiting their aggregate impact to below 0.7 pp.

The directional structure of H1 persists on the nested LinkedIn superset (ALIGN04): the same category ordering emerges with Programming & Development carrying the largest semantic deficit (1.39 pp [1.38, 1.41]) and Soft Skills again at 0.00 pp, while absolute magnitudes are smaller—consistent with two corpus-composition facts. First, free-text LinkedIn skills under-detect exact taxonomy keywords, so category demand shares are conservative; second, the same generic-term dominance documented for the SGI lowers technical coverage rates structurally. This check therefore supports the ordering of H1 while indicating that deficit magnitudes are corpus-conditional (Section V-E, item 7).

V. Discussion

A. Theoretical Implications

Hypothesis verdicts. Table VIII summarizes the three predictions derived in Section II-D. H1 (constructive alignment) is supported on the primary corpus and persists on the nested LinkedIn superset (one scrape family): technical categories carry the only nonzero deficits while soft skills are fully covered. H2 (terminology divergence) is supported by the primary ALIGN01/02 contrast (0.52 vs. 0.32), echoed within the same scrape family by the nested ALIGN04 check (0.37 vs. 0.14), and independently attested on curricular vocabulary by CURR01 (lexical 0–2.4% vs. semantic 30.4%)—and H3 (instrument robustness) is supported by strictly positive SGI and magnitude persistence on the nested LinkedIn superset (the lexical-above-semantic ordering is retained only as a sanity check, since every exact string match is also a cosine match of $1.0 \geq \tau$ by construction), and more strongly still by the matched-profile sensitivity showing identical SGI on both nested samples of the scrape family at equal academic covering-set size. Placement hypotheses H4–H6 and their benchmarks (STAT01, STAT02, PLAC01, INTL01) are evaluated as a benchmark audit in the companion article (`paper_placement/`).

TABLE VIII: Theory-Derived Hypotheses and Verdicts

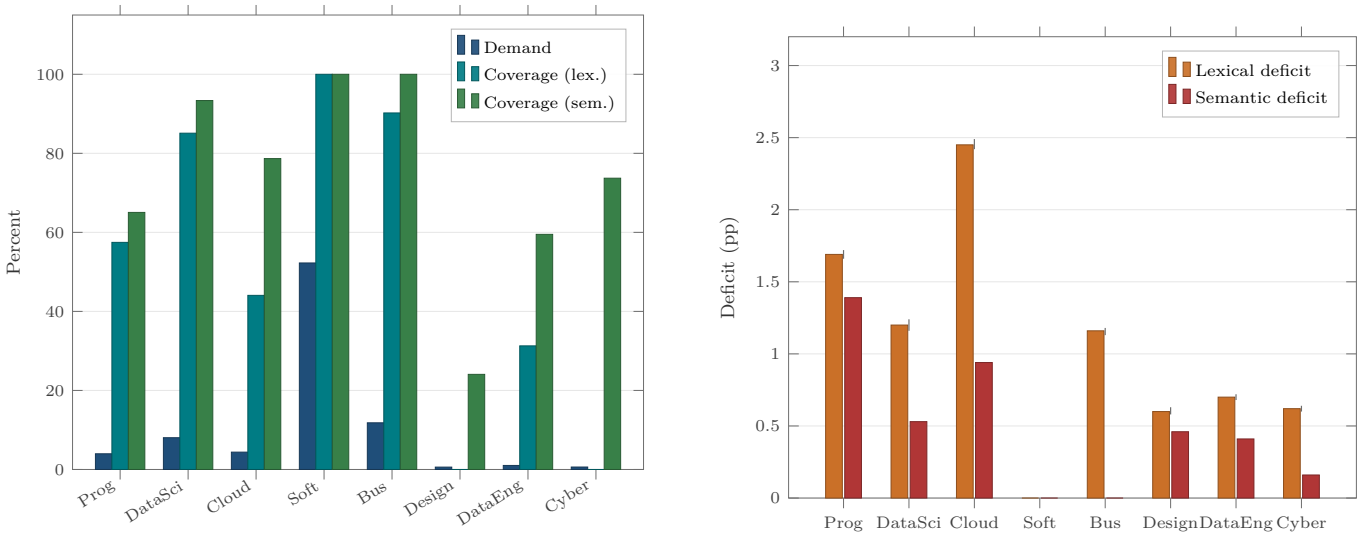

Hyp.	Source theory	Verdict (experiment)
H1	Constructive Alignment	Supported (ALIGN03, ALIGN04)
H2	Terminology divergence	Supported ×3 (ALIGN01/02, ALIGN04, CURR01)
H3	Instrument robustness	Supported (ALIGN04)

1) Terminology Divergence and Semantic Alignment: Studies evaluating curriculum alignment through exact keyword matching often report misalignment rates exceeding 50% [9]. Our findings qualify this observation. While exact string matching yields an apparent gap of 52.0%, dense vector embeddings reduce the estimated deficit to 32.0% at $\tau = 0.5$ (95% CI: [23.0%, 41.0%]). This divergence indicates that a portion of the measured gap arises from vocabulary differences: academic reference profiles and curricular descriptors often use conceptual terms (e.g., interpersonal communication or database principles), whereas job postings emphasize specific tool names or operational tasks. That expert-annotated lexical agreement is near chance ($\kappa = 0.112$; VALID01) while semantic agreement is substantial ($\kappa = 0.737$) shows this is a measurement property of keyword methods, not a modeling preference.

B. Institutional Factors in Curriculum Adaptation

The persistent 32.0% semantic deficit, and the domain-level deficits concentrated in Cloud Infrastructure (2.45 pp lexical; 0.94 pp semantic) and Programming & Development (1.69 pp lexical), are consistent with—though do not by themselves establish—institutional constraints in curriculum adaptation [26]:

1) **Curriculum Governance and Accreditation:** Formal degree reviews and accreditation bodies operate on multi-year cycles (typically 3 to 6 years). Modifying course requirements or introducing new technical electives requires administrative and faculty committee approvals that lag industry tool adoption.
2) **Faculty Development Latency:** Teaching rapidly evolving frameworks (e.g., container orchestration, distributed cloud platforms, specific ML toolchains) requires ongoing technical training, which institutional development budgets rarely prioritize over core research obligations.
3) **Infrastructure and Computing Costs:** Maintaining cloud accounts, GPU resources, and industry-grade data environments presents financial and op-

(a) Market demand vs. reference-profile coverage

(b) Deficit magnitude (pp) with 95% CI

Fig. 3: Skill-gap analysis across taxonomy categories (ALIGN03). (a) Market demand versus coverage by the academic reference profile (lexical and dense semantic at $\tau = 0.5$). (b) Deficit in percentage points of postings with 95% bootstrap confidence intervals. Cloud Infrastructure is the only Critical deficit under the relative-to-median severity rule.

erational hurdles for many computer science and engineering departments.

C. Implications and Recommendations

We organize recommendations for higher education, recruitment, and accreditation around the empirical findings:

For Higher Education Institutions (HEIs):

- *Integration of Modular Technical Credentials:* Cloud Infrastructure has the lowest reference-profile coverage of any category (44.1% lexical; 78.7% under semantic matching) and is the only Critical deficit, while Programming & Development retains a 1.69 pp deficit. Full degree restructuring may be too slow to keep pace with industry toolchains; HEIs can address this by embedding modular, vendor-neutral technical modules (e.g., containerization fundamentals, cloud storage basics) directly into existing operating systems and database courses.
- *Applied Project Work and Portfolio Development:* Because completed project work is the most portable evidence of applied technical ability, curricula should prioritize multi-term capstone projects that require version control, system deployment, and written documentation, giving students verifiable portfolios rather than relying on credentials alone (the portfolio-signal rationale of Section II).
- *Embedding Communication Skills into Technical Coursework:* The academic reference profile already covers soft-skill requirements in full (deficit 0.00 pp). The priority is therefore not new content but assessment: rather than relegating communication instruction to standalone electives, departments should integrate oral presentations, collaborative design reviews, and peer code reviews directly into core computing courses.

For Industry Recruiters:

- *Semantic Alignment in Recruitment Screening:* Because exact string matching produced a 52.0% gap compared with 32.0% under semantic alignment, keyword-based resume screening risks excluding candidates with equivalent conceptual training. Recruitment systems should evaluate semantic similarity rather than exact keyword matches when parsing academic coursework.

For Accreditation Bodies and Policymakers:

- *Adaptive Curriculum Guidelines:* Foundational requirements (Python, SQL) recur at similar shares in every corpus view in this study while specialized frameworks diversify across postings, a pattern consistent with rapid toolchain turnover. Accreditation bodies and professional societies (ACM, IEEE-CS) should issue regular modular addenda to curriculum guidelines to facilitate elective updates.
- *Regional Labor-Market Observatories:* Given the concentration of postings (85.2% US), educational authorities should maintain regional labor-market tracking to help institutions align elective offerings with local economic demand.

D. Reproducibility and Data Availability

Every quantitative result reported in this article originates from one of the registered experiments executed on NVIDIA GPU instances through Kaggle Notebooks; no table or figure is hand-transcribed. Table IX lists the experiment identifiers reported here, kernel references, and verification status; the retained-but-

TABLE IX: Experiment Registry: Provenance of All Reported Results (status per `results/registry.json`)

ID	Task	Kaggle GPU Kernel	Att.	Status

VALID01	External gold-standard matcher validation (VALID01)	`nihanshadman/sg-valid01-gold-a1`	1	USED_IN_MANUSCRIPT
ALIGN04	Nested-superset SGI re-check, LinkedIn (ALIGN04)	`tasnimjenny/sg-align04-crosscorpus-a4`	4	USED_IN_MANUSCRIPT
CURR01	CS2023 curriculum anchor validation (CURR01)	`rssiam/sg-curr01-cs2023-a2`	3	USED_IN_MANUSCRIPT

Each kernel receives an immutable input bundle from the public Kaggle dataset `studyhub991/skill-gap-inputs-v1` and writes `metrics.json` plus CSV artifacts; outputs are downloaded, schema- and sanity-verified (`experiments/verify.py`), and only `VERIFIED` outputs are used in this manuscript. Table and figure generation is automated by `experiments/make_latex.py` from those verified artifacts.

unused TRENDS01 entry is held in the supplement table (`paper/tables/tab_experiments_supplement.tex`); the placement-model experiments (STAT01, STAT02, PLAC01, INTL01) are reported in the companion benchmark audit (`paper_placement/`).

The analyses were implemented in Python 3.14.6 with `scikit-learn` 1.9.0, `statsmodels` 0.15.0, `sentence-transformers` 6.0.1 (`all-MiniLM-L6-v2`), `scipy` 1.18.1, `pandas` 3.0.5, and `numpy`; stratified cross-validation splits, bootstrap resamplings, and all estimators use fixed seeds (seed = 42; multi-seed robustness uses seeds 0–9). Complete experiment outputs are archived in the HuggingFace dataset `MoshinAli/skill-gap-experiments`, the runnable experiment suite and scheduler live in the project repository (`experiments/`), and all 15 source datasets are publicly accessible under open-access licenses (CC0, CC-BY 4.0, ODbL; Table I and `DATASET_MANIFEST.csv`).

E. Threats to Validity and Limitations

Several methodological constraints should be considered when interpreting these findings:

1) **Data Provenance & Benchmark Artifacts:** While Tier 1 datasets contribute 1.35M unique web-mined postings (the HuggingFace Skill Gap tables are a strict subset of the LinkedIn scrape rather than a second sample; Section IV-B2), the Tier 2 student benchmarks are apparently synthetic (generator-signature evidence; `datasets/synthetic_checks_output.json`) and are excluded from the gap findings here; their provenance, decision-boundary, and transfer audit is reported in the companion benchmark article (`paper_placement/`). The academic reference profile is drawn from 1,167 job postings in five occupational categories rather than from institutionally collected syllabi.
2) **Curriculum Proxy Limitations:** Academic skill demands were proxied through normalized occupational and educational reference profiles rather than direct, institutionally mined university syllabi across diverse global departments. Experiment CURR01 anchors this proxy to the CS2023 Body of Knowledge [50], quantifying both its validity (30.4% topical coverage, 49.6% of profile skills grounded in the guidelines) and its bound: coverage is concentrated in applied Knowledge Areas (HCI, Data Management, Software Engineering) and weak over the theoretical core (Algorithmic Foundations 12.6%, Mathematical Foundations 10.0%), so conclusions about applied skill coverage are anchored while claims about the full curricular core are not.
3) **Scope of Human Validation:** Matcher validity is established against published expert gold standards (SkillSpan→ESCO mappings; $\kappa = 0.737$ at $\tau = 0.5$; Section IV-B1) rather than in-house annotation of this specific corpus, and instrument robustness is supported by a nested-superset check (Section IV-B2); independent-rater annotation of the present skill pairs remains future work.
4) **Embedding Model and Threshold Sensitivity:** While Sentence-BERT mitigates surface vocabulary divergence, estimated alignment remains sensitive to cosine similarity cutoff selection (SGI = 20.0% at $\tau = 0.4$ versus 46.0% at $\tau = 0.7$) and to academic covering-set size (P): the matched-profile sensitivity in Section IV-B2 shows SGI levels shifting from 0.52/0.32 ($P = 100$) to 0.37/0.14 ($P = 500$) on both nested corpora of the scrape family, so cross-experiment SGI comparisons are valid only at equal (K, P).
5) **Geographic Concentration:** 85.2% of the LinkedIn posting corpus originates from the United States, skewing technical demand profiles toward Western, mature tech economies.
6) **Corpus Composition & Conditional Demand:** The 519K-posting skills corpus is dominated by generic, healthcare, and retail competencies (e.g., BLS/acls credentials and nursing appear among the Top-100 market tokens). Consequently, taxonomy-technical demand shares are modest (e.g., 3.97% of postings require at least one Programming skill), and the RQ3 deficits should be read as *coverage* gaps conditional on demand rather than as economy-wide demand shares. The nested LinkedIn check (ALIGN04) shows both sides of this conditioning: deficits shrink further on free-text skills (Programming 1.39 pp), and exact keyword taxonomy matching under-detects demand in corpora whose skill strings are not pre-normalized—so comparisons across the two annotation layers are valid for the *ordering* of deficits but not their absolute magnitudes.

7) **Automated Severity Calibration:** Because absolute domain deficits are small, the Critical/Moderate/Mild labels use a relative-to-median rule rather than externally anchored thresholds; different anchors would reassign labels, though the ranking of categories is invariant.

VI. Conclusion

Across 15 open datasets (1.35M real web-mined postings, 316K unverified aggregate rows, and 458K apparently synthetic benchmark rows), this empirical investigation—which proxies academic skill requirements with an employer-derived occupational reference profile rather than university syllabi—shows that profile–market misalignment is twofold. A substantial share of the apparent deficit reflects vocabulary divergence between academic descriptors and recruitment postings (the SGI falls from 52% to 32% under semantic alignment, and several domain deficits shrink by more than half), while substantive residual gaps remain concentrated in rapidly evolving technical areas, specifically Cloud Infrastructure and Programming & Development. The instrument supporting this claim is examined three ways: expert-gold agreement on published ESCO mappings ($\kappa = 0.737$), a nested-superset robustness check on 1.29M postings from the same scrape family (both indices strictly positive; identical SGI at matched academic covering-set size), and a computational anchor to the CS2023 curricular guidelines (embedding coverage concentrated in applied knowledge areas; no human line-by-line topic audit was performed). In practical terms, addressing this divide does not necessitate wholesale curriculum redesign. Integrating modular credentials into established courses, requiring verifiable applied project portfolios, and adopting semantic matching in hiring workflows offer feasible steps toward aligning academic preparation with contemporary workforce demands.
